  ↪ - a)));  
10    return ((p - a) * d - (b - a) * t).len() / d;  
11 }
```

Polygon area and Centroid

```
1 pair<point,ld> cenArea(const vector<point>& v) { assert(sz(v)  
  ↪ >= 3);  
2     point cen(0, 0); ld area = 0;  
3     forn(i,sz(v)) {  
4         int j = (i+1)%sz(v); ld a = cross(v[i],v[j]);  
5         cen = cen + a*(v[i]+v[j]); area += a; }  
6     return {cen/area/(ld)3,area/2}; // area is SIGNED  
7 }
```

Convex hull

- Complexity: $O(n \log n)$.

```
1 vector<point> convex_hull(vector<point> pts){  
2     sort(all(pts));  
3     pts.erase(unique(all(pts)), pts.end());  
4     vector<point> up, down;  
5     for (auto p : pts){  
6         while (sz(up) > 1 && acw(up.end()[-1] - up.end()[-2], p -  
  ↪ up.end()[-2])) up.pop_back();  
7         while (sz(down) > 1 && cw(down.end()[-1] - down.end()[-2],  
  ↪ p - down.end()[-2])) down.pop_back();  
8         up.pb(p), down.pb(p);  
9     }  
10    for (int i = sz(up) - 2; i >= 1; i--) down.pb(up[i]);  
11    return down;  
12 }
```

Point location in a convex polygon

- Complexity: $O(n)$ precalculation and $O(\log n)$ query.

```
1 void prep_convex_poly(vector<point>& pts){  
2     rotate(pts.begin(), min_element(all(pts)), pts.end());  
3 }  
4  
5 // 0 - Outside, 1 - Exclusively Inside, 2 - On the Border  
6 int in_convex_poly(point p, vector<point>& pts){  
7     int n = sz(pts);  
8     if (!n) return 0;  
9     if (n <= 2) return is_on_seg(p, pts[0], pts.back());  
10    int l = 1, r = n - 1;  
11    while (r - l > 1){  
12        int mid = (l + r) / 2;  
13        if (acw(pts[mid] - pts[0], p - pts[0])) l = mid;  
14        else r = mid;  
15    }  
16    if (!in_triangle(p, pts[0], pts[l], pts[l + 1])) return 0;  
17    if (is_on_seg(p, pts[l], pts[l + 1]) ||  
18        is_on_seg(p, pts[0], pts.back()) ||  
19        is_on_seg(p, pts[0], pts[l]))  
20        return 2;  
21    return 1;  
22 }
```

Point location in a simple polygon

- Complexity: $O(n)$.

```
1 // 0 - Outside, 1 - Exclusively Inside, 2 - On the Border  
2 int in_simple_poly(point p, vector<point>& pts){  
3     int n = sz(pts);  
4     bool res = 0;  
5     for (int i = 0; i < n; i++){  
6         auto a = pts[i], b = pts[(i + 1) % n];  
7         if (is_on_seg(p, a, b)) return 2;  
8         if (((a.y > p.y) - (b.y > p.y)) * cross(b - p, a - p) >  
  ↪ EPS){  
9             res ^= 1;  
10        }  
11    }  
12    return res;  
13 }
```

Minkowski Sum

- For two convex polygons P and Q , returns the set of points $(p + q)$, where $p \in P, q \in Q$.
- This set is also a convex polygon.
- Complexity: $O(n)$.

```
1 void minkowski_rotate(vector<point>& P){  
2     int pos = 0;  
3     for (int i = 1; i < sz(P); i++){  
4         if (abs(P[i].y - P[pos].y) <= EPS){  
5             if (P[i].x < P[pos].x) pos = i;  
6         }  
7         else if (P[i].y < P[pos].y) pos = i;
```

```

8     }
9     rotate(P.begin(), P.begin() + pos, P.end());
10 }
11 // P and Q are strictly convex, points given in
12 // ↪ counterclockwise order.
13 vector<point> minkowski_sum(vector<point> P, vector<point> Q){
14     minkowski_rotate(P);
15     minkowski_rotate(Q);
16     P.pb(P[0]);
17     Q.pb(Q[0]);
18     vector<point> ans;
19     int i = 0, j = 0;
20     while (i < sz(P) - 1 || j < sz(Q) - 1){
21         ans.pb(P[i] + Q[j]);
22         ld curmul;
23         if (i == sz(P) - 1) curmul = -1;
24         else if (j == sz(Q) - 1) curmul = +1;
25         else curmul = cross(P[i + 1] - P[i], Q[j + 1] - Q[j]);
26         if (abs(curmul) < EPS || curmul > 0) i++;
27         if (abs(curmul) < EPS || curmul < 0) j++;
28     }
29     return ans;
30 }

```

Half-plane intersection

- Given N half-plane conditions in the form of a ray, computes the vertices of their intersection polygon.
- Complexity: $O(N \log N)$.
- A ray is defined by a point p and direction vector dp . The half-plane is to the **left** of the direction vector.

```

1 // Extra functions needed: point operations, dot, cross
2 const ld EPS = 1e-9;
3
4 int sgn(ld a){
5     return (a > EPS) - (a < -EPS);
6 }

22 }

```

Aho-Corasick Trie

- Given a set of strings, constructs a trie with suffix links.
- For a particular node, *link* points to the longest proper suffix of this node that's contained in the trie.
- nxt* encodes suffix links in a compressed format:
 - If vertex *v* has a child by letter *x*, then *trie[v].nxt[x]* points to that child.
 - If vertex *v* doesn't have such child, then *trie[v].nxt[x]* points to the suffix link of that child if we would actually have it.
- Facts:** suffix link graph can be seen as a tree; terminal link tree has height $O(\sqrt{N})$, where *N* is the sum of strings' lengths.
- Usage:** add all strings, then call *add_links()*.

```

1 const int S = 26;
2
3 // Function converting char to int.
4 int ctoi(char c){
5     return c - 'a';
6 }
7

66 }

```

Suffix Automaton

- Given a string S , constructs a DAG that is an automaton of all suffixes of S .
- The automaton has $\leq 2n$ nodes and $\leq 3n$ edges.
- Properties (let all paths start at node 0):
 - Every path represents a unique substring of S .
 - A path ends at a terminal node iff it represents a suffix of S .
 - All paths ending at a fixed node v have the same set of right endpoints of their occurrences in S .
 - Let $endpos(v)$ represent this set. Then, $link(v) := u$ such that $endpos(v) \subset endpos(u)$ and $|endpos(u)|$ is smallest possible. $link(0) := -1$. Links form a tree.
 - Let $len(v)$ be the longest path ending at v . All paths ending at v have distinct lengths: every length from interval $[len(link(v)) + 1, len(v)]$.
- One of the main applications is dealing with **distinct** substrings. Such problems can be solved with DFS and DP.
- Complexity: $O(|S| \cdot \log |\Sigma|)$. Perhaps replace map with vector if $|\Sigma|$ is small.

```

```

Biconnected Components and Block-Cut Tree

- Biconnected components are the ones that have no articulation points.
- They are defined by edge sets that are “bounded” by articulation points in the original graph.
- The corresponding vertex sets are stored in *comps*.
- Block-Cut tree is constructed by creating a fictive node for each component, and attaching edges to its members.
- Articulation points in the original graph are the non-leaf non-fictive nodes in the BC tree.
- Complexity: $O(n)$.

```

1 // Usage: pass in adjacency list in 0-based indexation.

```

```

2 // Return: adjacency list of block-cut tree (nodes 0...n-1
↳ represent original nodes, the rest are component nodes).
3 vector<vi> biconnected_components(vector<vi> g) {

CRT

- $\text{crt}(a, m, b, n)$ computes x such that $x \equiv a \pmod{m}$, $x \equiv b \pmod{n}$
- If $|a| < m$ and $|b| < n$, x will obey $0 \leq x < \text{lcm}(m, n)$.
- Assumes $mn < 2^{62}$.
- $O(\max(\log m, \log n))$

```

1 ll crt(ll a, ll m, ll b, ll n) {
2     if (n > m) swap(a, b), swap(m, n);
3     ll x, y, g = euclid(m, n, x, y);
4     assert((a - b) % g == 0); // else no solution
5     // can replace assert with whatever needed
6     x = (b - a) % n * x % n / g * m + a;
7     return x < 0 ? x + m*n/g : x;
8 }

```

Linear Sieve

- Mobius Function

Simplex method for linear programs

- Maximize $c^T x$ subject to $Ax \leq b$, $x \geq 0$.
- Returns $-\infty$ if there is no solution, $+\infty$ if there are arbitrarily good solutions, or the maximum value of $c^T x$ otherwise. The (arbitrary) input vector is set to an optimal x (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that $x = 0$ is viable.
- Complexity: $O(NM \cdot \text{pivots})$. $O(2^n)$ in general (very hard to achieve).

```

Matroid Intersection

- Matroid is a pair $\langle X, I \rangle$, where X is a finite set and I is a family of subsets of X satisfying:
 1. $\emptyset \in I$.
 2. If $A \in I$ and $B \subseteq A$, then $B \in I$.
 3. If $A, B \in I$ and $|A| > |B|$, then there exists $x \in A \setminus B$ such that $B \cup \{x\} \in I$.
- Set S is called **independent** if $S \in I$.
- **Common matroids:** uniform (sets of bounded size); colorful (sets of colored elements where each color only appears once); graphic (acyclic sets of edges in a graph); linear-algebraic (sets of linearly independent vectors).
- **Matroid Intersection Problem:** Given two matroids, find the largest common independent set.
- A matroid has 3 functions:
 - *check(int x)*: returns if current matroid can add x without becoming dependent.
 - *add(int x)*: adds an element to the matroid (guaranteed to never make it dependent).
 - *clear()*: sets the matroid to the empty matroid.
- The matroid is given an *int* representing the element, and is expected to convert it (e.g: color or edge endpoints)
- Pass the matroid with more expensive add/clear operations to M1.
- **Complexity:** $R^2 \cdot N \cdot (M2.add + M1.check + M2.check) + R^3 \cdot (M1.add) + R^2 \cdot (M1.clear) + R \cdot N \cdot (M2.clear)$, where $R = \text{answer}$.

```

Convex Hull Trick

- Allows to insert a linear function to the hull in (1) and get the minimum/maximum value of the stored function at a point in $O(\log n)$.
- NOTE: The lines must be added in the order of decreasing/increasing gradients. CAREFULLY CHECK THE SETUP BEFORE USING!
- IMPORTANT: DO NOT MODIFY TO QUERY MAX, IT WILL BREAK

```
1  struct line{
2      ll k, b;
3      ll f(ll x){
4          return k * x + b;
5      };
6  };
7
8  vector<line> hull;
9
10 void add_line(line nl){
11     if (!hull.empty() && hull.back().k == nl.k){
12         nl.b = min(nl.b, hull.back().b);
13         hull.pop_back();
14     }
15     while (sz(hull) > 1){
16         auto& l1 = hull.end()[-2], l2 = hull.back();
17         if ((nl.b - l1.b) * (l2.k - nl.k) >= (nl.b - l2.b) * (l1.k
18             ↪ - nl.k)) hull.pop_back();
19         else break;
20     }
21     hull.pb(nl);
22 }
23
24 ll get(ll x){
25     int l = 0, r = sz(hull);
26     while (r - l > 1){
27         int mid = (l + r) / 2;
28         if (hull[mid - 1].f(x) >= hull[mid].f(x)) l = mid;
29         else r = mid;
30     }
31     return hull[l].f(x);
32 }
```

Li-Chao Segment Tree

- allows to add linear functions in any order and query minimum/maximum value of those at a point, all in $O(\log n)$.
- Clear: clear()

```
1  const ll INF = 1e18; // Change the constant!
2  struct LiChaoTree{

Persistent Segment Tree

- for RSQ

```

1 struct Node {
2     ll val;
3     Node *l, *r;
4
5     Node(ll x) : val(x), l(nullptr), r(nullptr) {}
6     Node(Node *ll, Node *rr) {
7         l = ll, r = rr;
8         val = 0;
9         if (l) val += l->val;
10        if (r) val += r->val;

```

```

11    }
12    Node(Node *cp) : val(cp->val), l(cp->l), r(cp->r) {}
13 };
14 const int N = 2e5 + 20;
15 ll a[N];
16 Node *roots[N];
17 int n, cnt = 1;
18 Node *build(int l = 1, int r = n) {
19     if (l == r) return new Node(a[l]);
20     int mid = (l + r) / 2;
21     return new Node(build(l, mid), build(mid + 1, r));
22 }
23 Node *update(Node *node, int val, int pos, int l = 1, int r =
24     ↪ n) {
25     if (l == r) return new Node(val);
26     int mid = (l + r) / 2;
27     if (pos > mid)

38     ↪ mid + 1, r);
39 }

```

Dynamic Programming

Sum over Subset DP

- Computes $f[A] = \sum_{B \subseteq A} a[B]$.
- Complexity: $O(2^n \cdot n)$.

```

1 forn(i, (1 << n)) f[i] = a[i];
2 forn(i, n) for (int mask = 0; mask < (1 << n); mask++) if
3     ↪ ((mask >> i) & 1){
4         f[mask] += f[mask ^ (1 << i)];
5     }

```

Divide and Conquer DP

- Helps to compute 2D DP of the form:
- $dp[i][j] = \min_{0 \leq k \leq j-1} (dp[i-1][k] + cost(k+1, j))$
- **Necessary condition:** let $opt(i, j)$ be the optimal k for the state (i, j) . Then, $opt(i, j) \leq opt(i, j+1)$.
- **Sufficient condition:** $cost(a, d) + cost(b, c) \geq cost(a, c) + cost(b, d)$ where $a < b < c < d$.
- Complexity: $O(M \cdot N \cdot \log N)$ for computing $dp[M][N]$.

```

1 vll dp_old(N), dp_new(N);
2
3 void rec(int l, int r, int optl, int optr){
4     if (l > r) return;
5     int mid = (l + r) / 2;
6     pair<ll, int> best = {INF, optl};
7     for (int i = optl; i <= min(mid - 1, optr); i++){ // If k
8     ↪ can be j, change to "i <= min(mid, optr)".
9         ll cur = dp_old[i] + cost(i + 1, mid);
10        if (cur < best.fi) best = {cur, i};
11    }
12    dp_new[mid] = best.fi;
13
14    rec(l, mid - 1, optl, best.se);
15    rec(mid + 1, r, best.se, optr);
16 }
17
18 // Computes the DP "by layers"
19 fill(all(dp_old), INF);
20 dp_old[0] = 0;

```

```

20 while (layers--){
21     rec(0, n, 0, n);
22     dp_old = dp_new;
23 }

```

- Do something instead of nothing, stay organized
- Write stuff down!
- Don't get stuck on one approach!

Knuth's DP Optimization

- Computes DP of the form
- $dp[i][j] = \min_{i \leq k \leq j-1} (dp[i][k] + dp[k+1][j] + cost(i, j))$
- **Necessary Condition:** $opt(i, j-1) \leq opt(i, j) \leq opt(i+1, j)$
- **Sufficient Condition:** For $a \leq b \leq c \leq d$, $cost(b, c) \leq cost(a, d)$ AND $cost(a, d) + cost(b, c) \geq cost(a, c) + cost(b, d)$
- Complexity: $O(n^2)$

```

1  int N;
2  int dp[N][N], opt[N][N];
3  auto C = [&](int i, int j) {
4      // Implement cost function C.
5  };
6  forn(i, N) {
7      opt[i][i] = i;
8      // Initialize dp[i][i] according to the problem
9  }
10 for (int i = N-2; i >= 0; i--) {
11     for (int j = i+1; j < N; j++) {
12         int mn = INT_MAX;
13         int cost = C(i, j);
14         for (int k = opt[i][j-1]; k <= min(j-1, opt[i+1][j]); k++)
15             ↪ {
16                 if (mn >= dp[i][k] + dp[k+1][j] + cost) {
17                     opt[i][j] = k;
18                     mn = dp[i][k] + dp[k+1][j] + cost;
19                 }
20             }
21         dp[i][j] = mn;
22     }
23 }

```

Miscellaneous

Ordered Set

```

1  #include <ext/pb_ds/assoc_container.hpp>
2  #include <ext/pb_ds/tree_policy.hpp>
3  using namespace __gnu_pbds;
4  typedef tree<int, null_type, less<int>, rb_tree_tag,
5      ↪ tree_order_statistics_node_update> ordered_set;

```

Measuring Execution Time

```

1  ld tic = clock();
2  // execute algo...
3  ld tac = clock();
4  // Time in milliseconds
5  cerr << (tac - tic) / CLOCKS_PER_SEC * 1000 << endl;
6  // No need to comment out the print because it's done to cerr.

```

Setting Fixed D.P. Precision

```

1  cout << setprecision(d) << fixed;
2  // Each number is rounded to d digits after the decimal point,
   ↪ and truncated.

```

Common Bugs and General Advice

- Check overflow, array bounds
- Check variable overloading
- Check special cases (n=1?)
